INTRODUCTION

Biscayne Bay, Florida was sampled during June, 1996. One aspect of this evaluation was benthic community characterization, which was accomplished via sample collection by National Oceanic and Atmospheric Administration (NOAA) personnel and laboratory and data analysis by Barry A. Vittor & Associates, Inc. (BVA).

METHODS

Sample Collection And Handling

A Young dredge (area = 0.04 m²) was used to collect replicate bottom samples at each of 40 stations in Biscayne Bay. Macrofaunal samples were sieved through a 0.5-mm mesh screen and preserved with 10% formalin on ship. Macrofaunal samples were transported to the BVA laboratory in Mobile, Alabama.

Sediment Analysis

Sediment texture was determined at half-phi intervals using the hydrometer technique for fractions smaller than 44 µm and nested sieves for larger particle fractions. Texture parameters computed included percent gravel, sand, and silt /clay. Total organic carbon (TOC) content was measured as ash-free dry weight expressed as a percentage.

Macrofaunal Sample Analysis

In the laboratory of BVA, benthic samples were inventoried, rinsed gently through a 0.5 mm mesh sieve to remove preservatives and sediment, stained with Rose Bengal, and stored in 70% isopropanol solution until processing. Sample material (sediment, detritus, organisms) was placed in white enamel trays for sorting under Wild M-5A dissecting microscopes. All macroinvertebrates were carefully removed with forceps and placed in labelled glass vials containing 70% isopropanol. Each vial represented a major taxonomic group (e.g. Polychaeta, Mollusca, Arthropoda). All sorted macroinvertebrates were identified to the lowest practical

identification level (LPIL), which in most cases was to species level unless the specimen was a juvenile, damaged, or otherwise unidentifiable. The number of individuals of each taxon, excluding fragments, was recorded. A voucher collection was prepared, composed of representative individuals of each species not previously encountered in samples from the region.

DATA ANALYSIS

All data generated as a result of laboratory analysis of macroinfauna samples were first coded on data sheets. Enumeration data were entered for each species according to station and replicate. These data were reduced to a data summary report for each station, which included a taxonomic species list and benthic community parameters information. Archive data files of species identification and enumeration were prepared.

The QA/QC report for the Biscayne Bay samples is given in the Appendix.

The analytical methodologies utilized for this study were similar to those used in other benthic community characterization reports prepared for NOAA. Macroinfaunal characterization involves an evaluation of several biological community structure parameters (e.g., species abundance, species composition and species diversity indices) during initial data reduction, followed by pattern and classification analysis for delineation of taxa assemblages. Since species are distributed along environmental gradients, there are generally no distinct boundaries between communities. However, the relationships between habitats and species assemblages often reflect the interactions of physical and biological factors and indicate major ecological trends.

Assemblage Structure

Several numerical indices were chosen for analysis and interpretation of the macroinfaunal data. Selection was based primarily on the ability of the index to provide a meaningful summary of data, as well as the applicability of the index to the characterization of the benthic community. Infaunal abundance is reported as the total number of individuals per station and the total number

of individuals per square meter (= density). Taxa richness is reported as the total number of taxa represented in a given station collection.

Taxa diversity, which is often related to the ecological stability and environmental "quality" of the benthos, was estimated by the Pielou's Index (Pielou, 1966), according to the following formula:

$$H' = - \sum_{i=1}^S p_i (\ln p_i)$$

where, S = is the number of taxa in the sample,

i = is the i'th taxa in the sample, and

p_i = is the number of individuals of the i'th taxa divided by the total number of

individuals in the sample.

Taxa diversity within a given community is dependent upon the number of taxa present (taxa richness) and the distribution of all individuals among those taxa (equitability or evenness).

In order to quantify and compare faunal equitability to taxa diversity for a given area, Pielou's

Index J' (Pielou, 1966) was calculated as $J' = H'/\ln S$, where $\ln S = H'_{\max}$, or the maximum

possible diversity, when all taxa are represented by the same number of individuals;

thus, $J' = H' /H'_{\max}$.

Macrofaunal data were graphically and statistically analyzed to identify any differences in density between stations. Data for total density were variously transformed and tested for normality (Shapiro-Wilk W; SAS Institute, 1995). Data could not be normalized with standard transformations [e.g. $\ln(x+1)$, $(x+1)$] and were analyzed using non-parametric methods (SAS Institute, 1995).

Faunal Similarities

Cluster analysis was performed on the faunal data to examine between-station differences at the Florida Bay stations and to compare faunal composition at each station within the study area. Both normal and inverse cluster analyses were used in this study. Normal analysis (sometimes

called Q-analysis) treats samples as individual observations, each being composed of a number of attributes (i.e. the various taxa from a given sample). Normal analysis is instructive in helping to ascertain community structure and to infer specific ecological conditions between sampling stations from the relative distributions of species. Inverse clustering (termed R-analysis) is based on taxa as individuals, each of which is characterized by its relative abundance in the various samples. This type of analysis is commonly used to identify species groupings with particular habitats or environmental conditions.

Cluster analysis of both station collections (normal analysis) and taxa (inverse analysis) was performed using the average linkage method (SAS Institute 1997). In this method, the distance between two clusters is the average distance between pairs of observations, one in each cluster. Taxa used in these analyses were selected according to their percent abundance in the assemblage. Total densities for each of the selected taxa at a given station were ln transformed [$x=\ln(x+1)$] before the analyses.

HABITAT CHARACTERISTICS

Sediment data for the 40 stations are given in Table 1 and Figures 1, 2, and 3. Sediment composition at the 40 stations varied considerably from 78% silt (sandy silt) at Station 178 to greater than 98% sand at Stations 216 and 218 (Table 1; Figure 1); however, the sediment at the majority of stations was predominantly sand or silty sand (Figure 2). The total organic carbon (TOC) fraction of the sediment ranged from 0.69% at Station 216 to 16.2% at Station 208 (Table 1; Figure 3).

BENTHIC COMMUNITY CHARACTERIZATION

Faunal Composition, Abundance, And Community Structure

Table 2 provides a complete phylogenetic listing for all stations as well as data on taxa abundance and station occurrence. Four Microsoft TMExcel 5.0 (Macintosh version) spreadsheets are being provided separately to NOAA which include: raw data on taxa abundance and density by

Ph = Phoronida

R = Rhynchocoela

S = Sipuncula

replicate, a complete taxonomic listing with station abundance and occurrence and QA/QC comments, a major taxa table with overall taxa abundance, and an assemblage parameter table including data on mean number of taxa, mean density, taxa diversity and taxa evenness by station.

A total of 54,424 organisms, representing 775 taxa, were identified from the 40 stations (Table 3). Polychaetes were the most numerous organisms present representing 35.4% of the total assemblage, followed in abundance by gastropods (26.2%) and malacostracans (17.5%). Polychaetes represented 36.9% of the total number of taxa followed by malacostracans (24.1%), gastropods (14.9%), and bivalves (12.0%) (Table 3). The percentage abundance of the major taxa at the 40 stations is given in Table 4.

The dominant taxa collected from the samples were the gastropods, *Caecum pulchellum*, and *Tarebia granifera*, and the polychaete, *Fabricinuda trilobata*, representing 17.0%, 5.4% and 4.9% of the total number of individuals, respectively (Table 2). *Tarebia granifera*, the second most abundant taxa, was found at only one station (202). The annelid class, Oligochaeta (LPIL), the Rhynchocoela (LPIL) and the mollusc class, Gastropoda (LPIL) were the most widely distributed taxa being found at 97.5%, 95.0% and 92.5% of the stations, respectively (Table 2). The distribution of dominant taxa representing >10% of the total assemblage at each station is given in Table 5.

Station mean density and mean number of taxa data are given in Table 1 and Figures 4 and 5. Mean densities ranged from 183 organisms·m⁻² at Station 208 to 34,683 organisms·m⁻² at Station 175 (Table 1; Figure 5). The mean number of taxa per replicate ranged from 3.0 at Station 208 to 143.0 at Station 175 (Table 1; Figure 6).

There was a significant positive correlation between station mean density data and total taxa per replicate and % gravel + sand in the sediment, and a significant negative correlation with % silt + clay in the sediments and sediment TOC (Table 6; Figures 6, 7, 8). The number of taxa per replicate was positively correlated with % gravel + sand in the sediment and negatively correlated

Table 3. Summary of abundance of major taxonomic groups for the Biscayne Bay stations, June 1996.

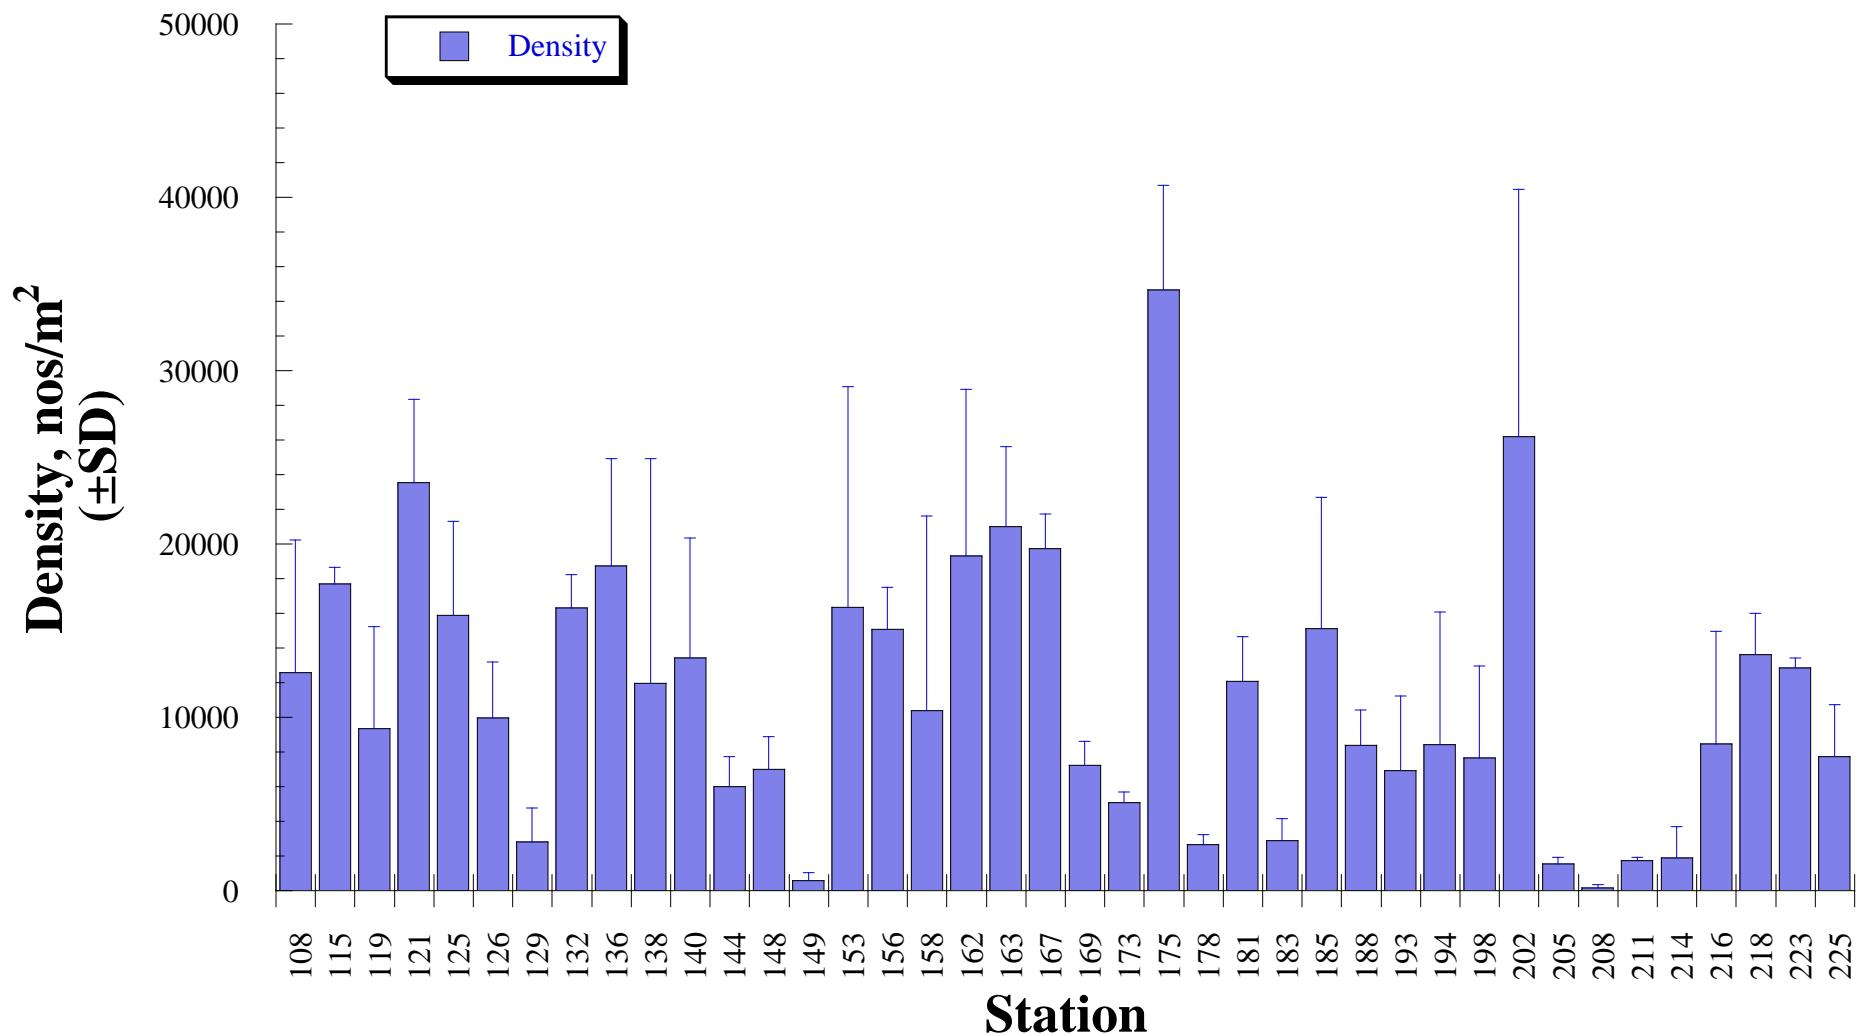

Figure 5. Mean number of macroinvertebrate taxa per replicate for the Biscayne Bay stations, June 1996.

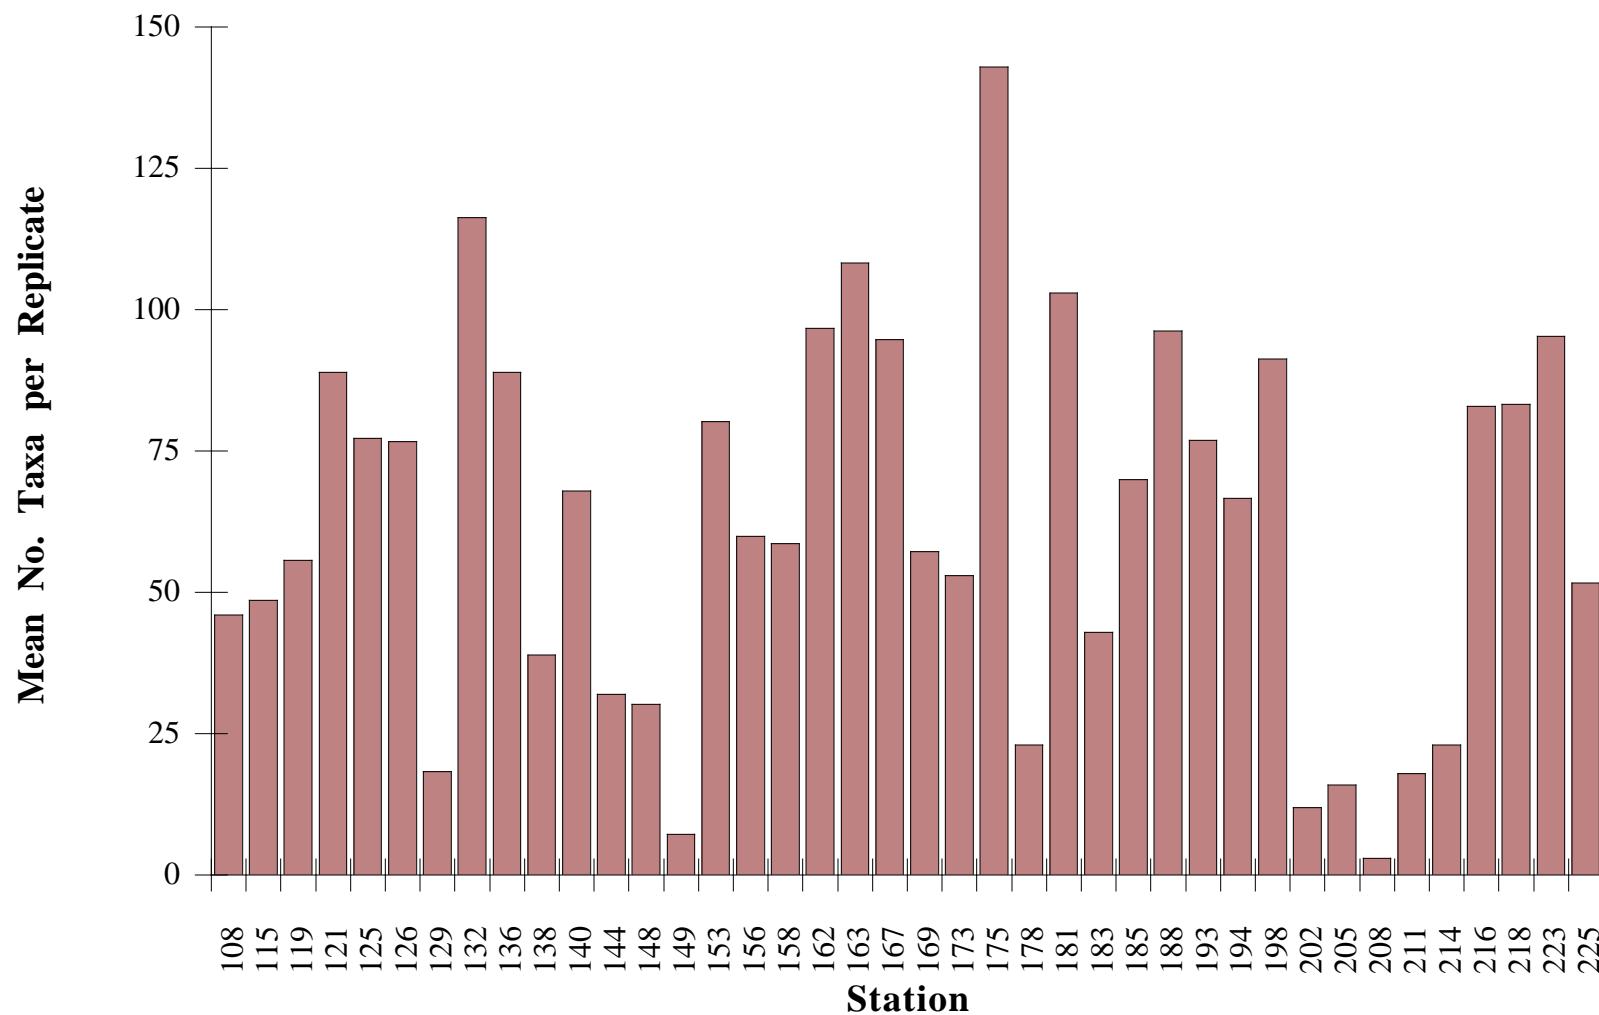

Table 6. Correlation coefficients for the Biscayne Bay data, June 1996.

Variable	by Variable	Correlation Spearman's Rho	Significance Probability
Density	total taxa	0.5938	<.0001
	% gravel & sand	0.5418	0.0003
	% silt & clay	- 0.549	0.0002
	TOC	- 0.5002	0.001
Total Taxa	% gravel & sand	0.3668	0.0199
	% silt & clay	- 0.3606	0.0223
	TOC	- 0.5247	0.0005
% Gravel & Sand	% silt & clay	- 0.9983	<.0001
	TOC	- 0.7192	<.0001
% Silt & Clay	TOC	0.7132	<.0001

Figure 6. Mean macroinvertebrate densities versus the mean number of macroinvertebrate taxa per replicate for the Biscayne Bay stations, June 1996.

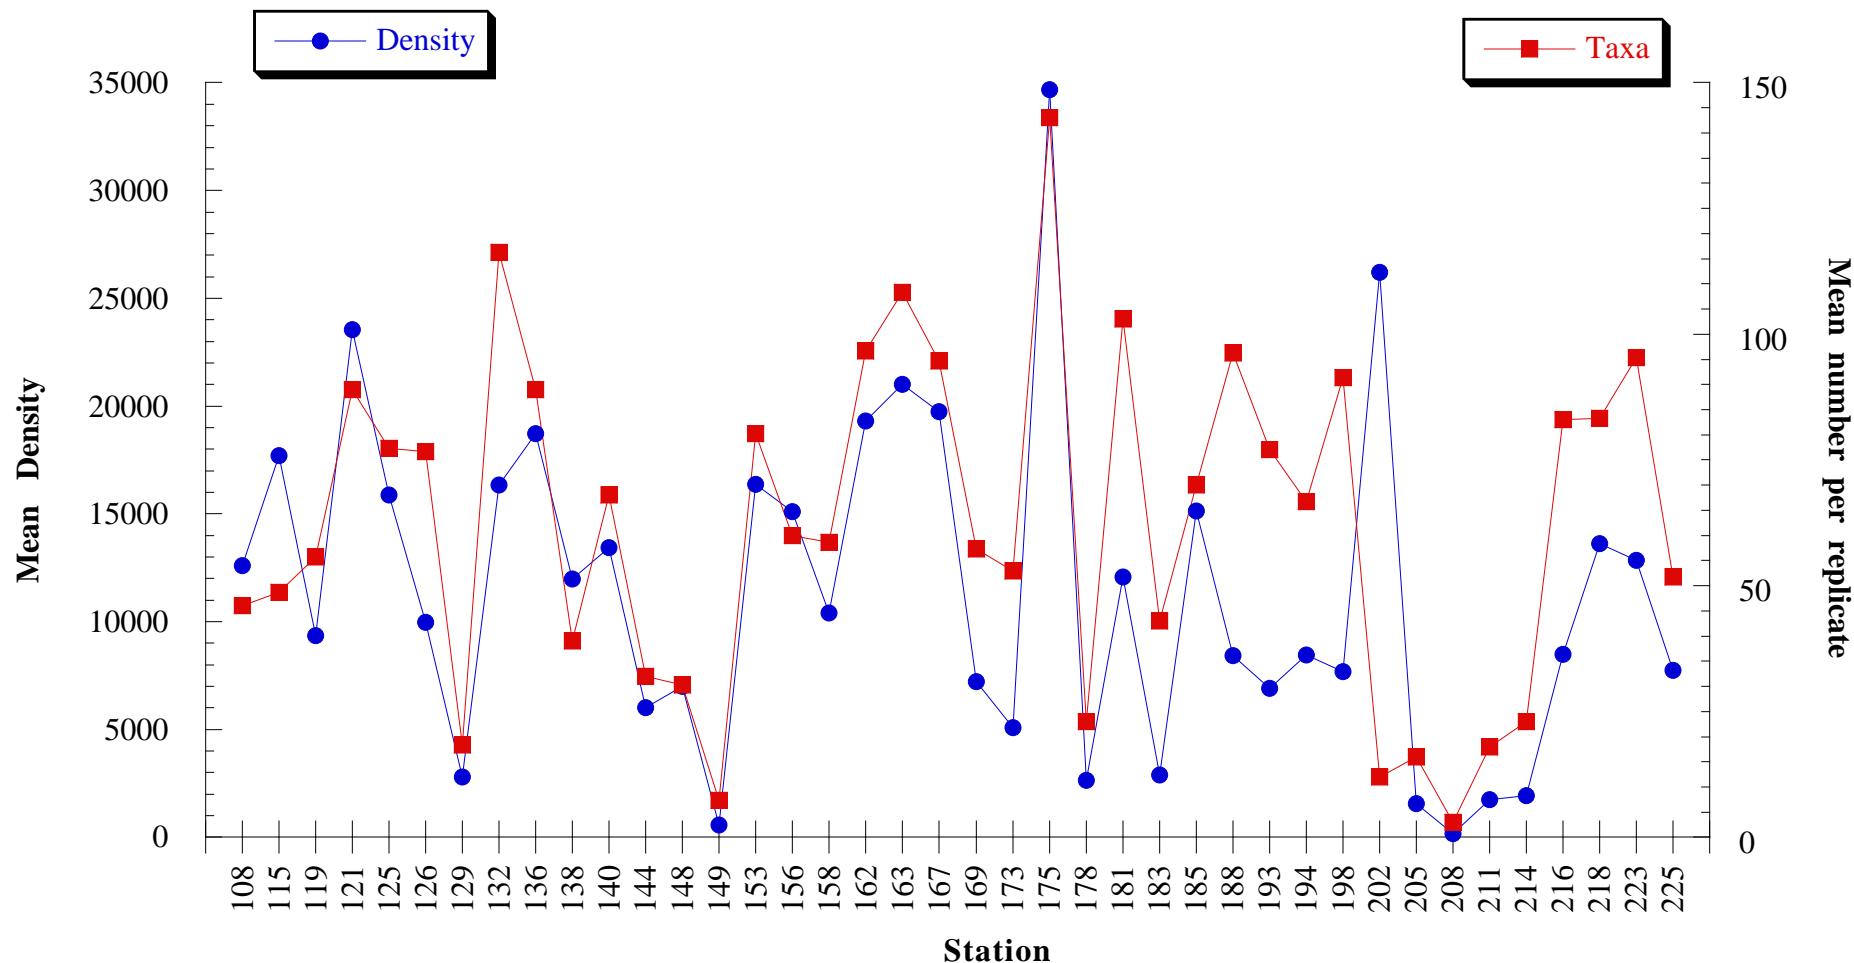

Figure 7. Mean macroinvertebrate densities versus the percent gravel/sand content of the sediment for the Biscayne Bay stations, June 1996

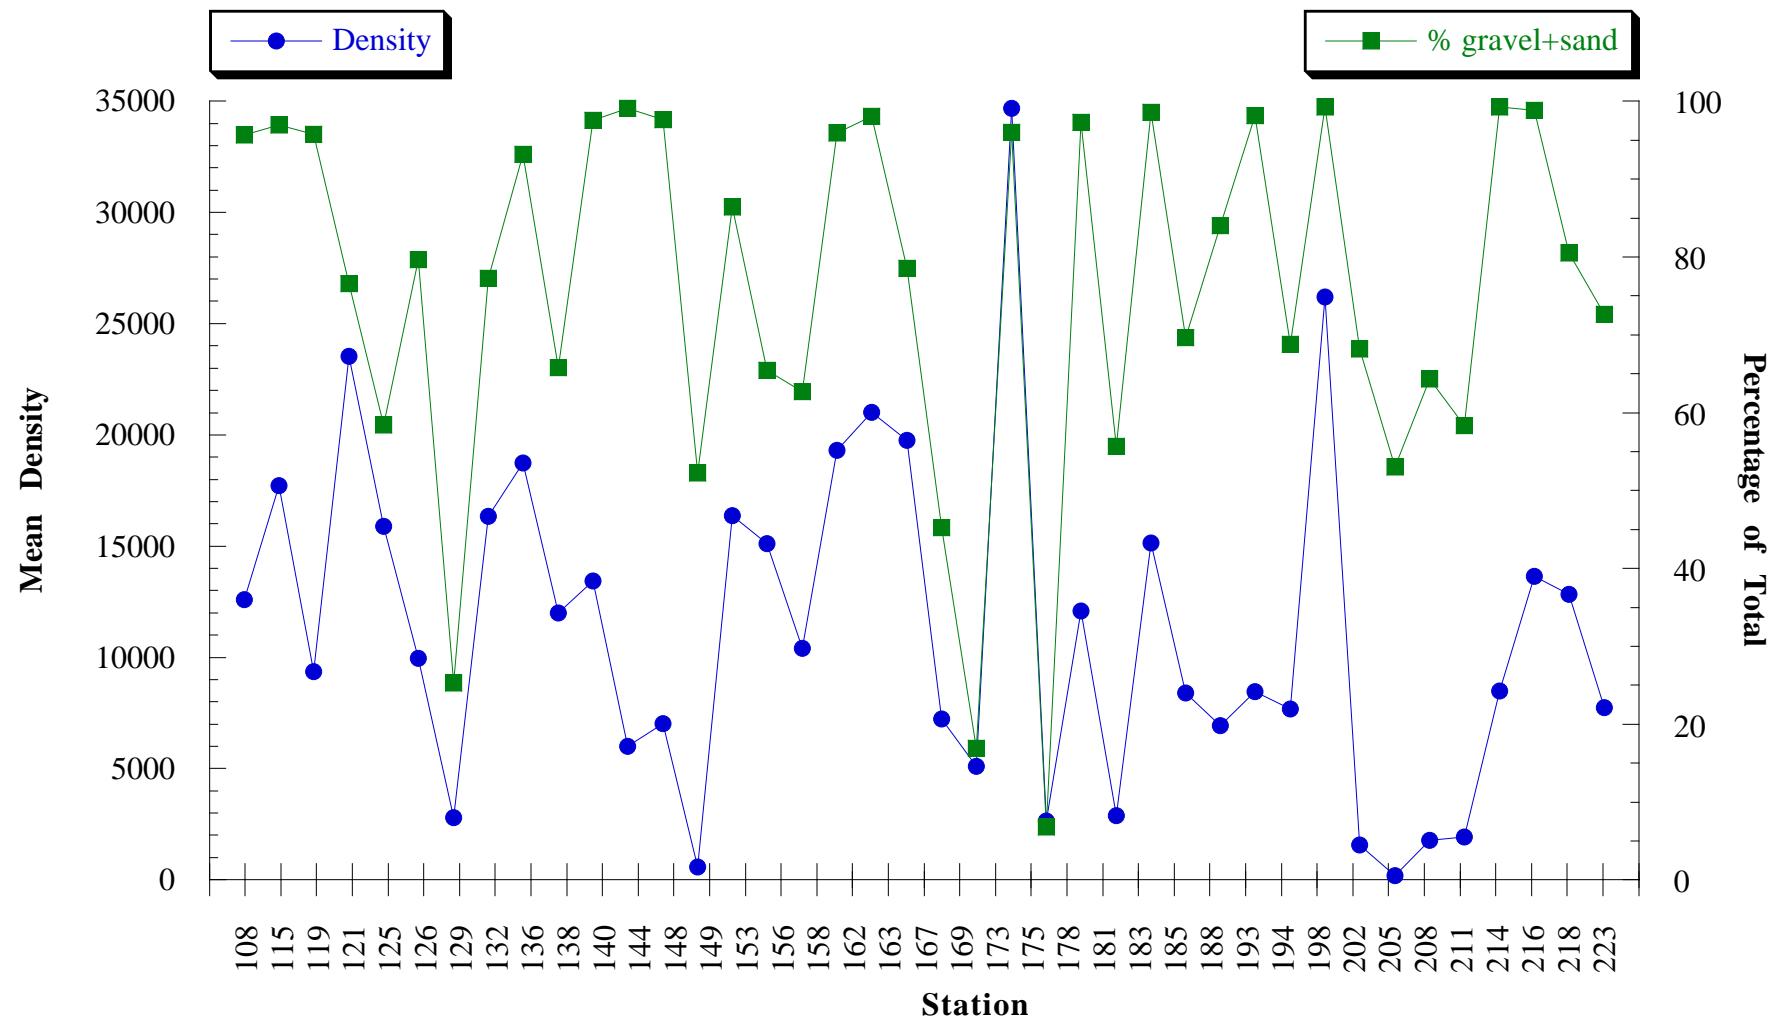

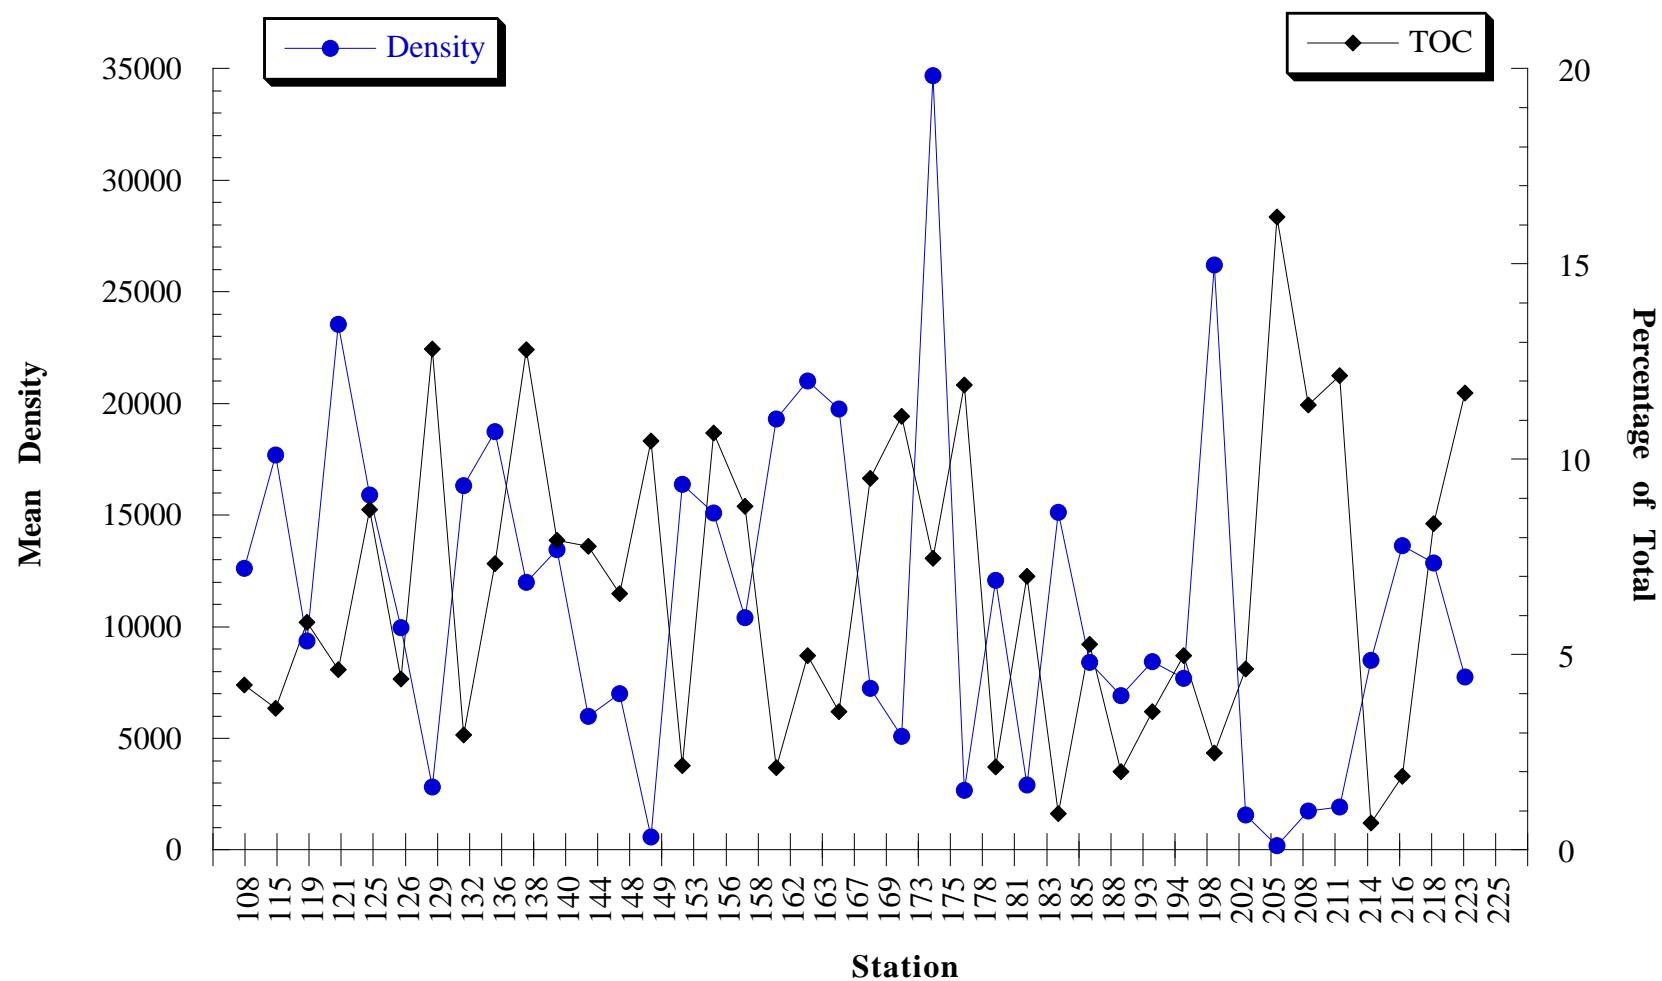

Figure 8. Mean macroinvertebrate densities versus percent sediment total organic carbon (TOC) for the Biscayne Bay stations, June 1996

with % silt + clay in the sediments and sediment TOC (Table 6; Figure 9). There were additional significant correlations between various physical and chemical parameters:

% gravel + sand was inversely correlated with % silt + clay and TOC; and % silt + clay was positively correlated with TOC (Table 6).

Taxa diversity and evenness are given in Table 1 and Figure 10. Taxa diversity (H') ranged from 0.41 at Station 202 to 4.65 at Station 198. Taxa evenness (J') values ranged from 0.14 at Station 202 to 0.89 at Station 198 (Table 1; Figure 10).

Cluster Analysis

Normal (stations) and inverse (species) cluster analyses were performed on the Biscayne Bay data set and displayed as dendograms (Figures 11 and 12). Selection of the species included in the analyses was based on a minimum representation of 0.4% of total individuals which encompassed 55 taxa. These taxa accounted for 69.8% of the macrofaunal assemblage collected.

Numerical clustering of the 40 stations can be interpreted at a five-group level. One group contained only Station 202 with a macrofaunal assemblage dominated by the mollusc, *Tarebia granifera*; station 202 also had the lowest diversity and evenness of the 40 stations (Table 1; Figure 10). A second group contained only station 175 which had a mean density 25% higher than the next highest. A third group contained stations 115 and 185 characterized by the highest densities of the most abundant taxa in this study, *Caecum pulchellum*. A fourth group contained Stations 108, 167, 119, 148, 140, 138 and 121 and was characterized by high densities of *C. pulchellum* (Figure 11). The final group contained the remaining 29 stations with a mixed macrofaunal assemblage.

Clustering of the 55 taxa at the 40 stations can be interpreted at a five-group level (Figure 12). Four of the five groups contained only one taxa each. One group included the taxon *Tarebia granifera* found in high numbers only at Station 202 (Figure 12; Table 2). A second group contained only *Fabricinuda trilobata* found in high densities at Stations 108, 125 and 175 (Figure

Figure 9. Mean number of macroinvertebrate taxa per replicate versus percent sediment total organic carbon (TOC) for the Biscayne Bay stations, June 1996.

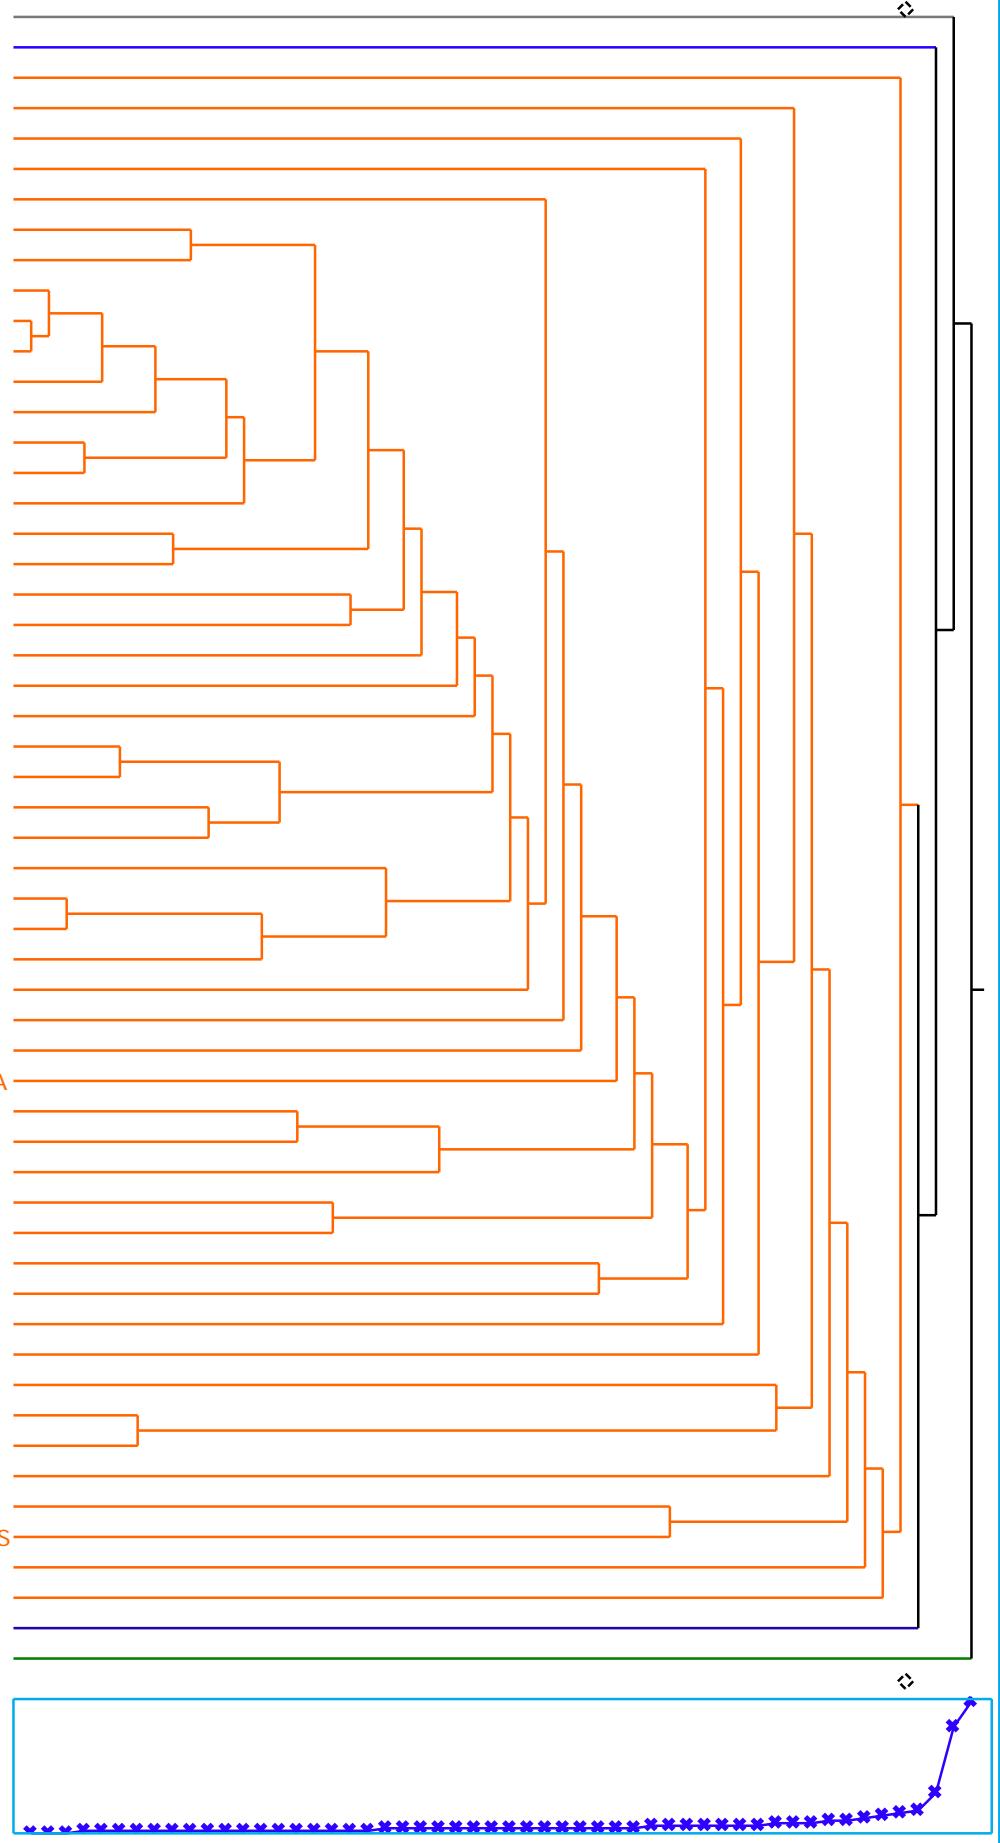

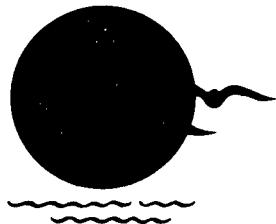

Figure 12. Inverse (taxa) classification analysis for the Biscayne Bay stations, June 1996

12). A third group consisted only of *Leptochelia* (LPIL) a large genus well represented in southern Florida which also accounted for nearly 3% of the total individuals collected (Figure 12; Table 2). A fourth group consisted only of *Ceacum pulchellum* (Figure 12), and was the most abundant taxa collected in the 1996 sampling effort, accounting for 16.9% of all individuals and occurring at 87.5% of stations (Table 2). The remaining 51 taxa fell into one large group containing a diverse array of taxa collected across the 40 stations (Figure 12).

QUALITY ASSURANCE STATEMENT

Client/Project: NOAA

Work Assignment Title: Biscayne Bay 1996

Work Assignment Number: BB 96 MR

Task Number: 5

Description of Data Set or Deliverable: 123 Benthic macroinvertebrate samples collected in
May and June of 1996; Young Dredge grabs.

Description of audit and review activities: Judged accuracy rates were well above standard levels for sorting and taxonomy. Laboratory QC reports were completed. Copies of reports and QC results follow (see attachment). All taxonomic data were entered into computer and printed. This list was checked for accuracy against original taxonomic data sheets.

Description of outstanding issues or deficiencies which may affect data quality: None
